Clamav funcation call flow(AC scan)

ac scan with regex signature

by eqmcc

The call flow

When Clamav doing specific file scan (clamscan.c), there are following procedures:

- Initialize data structures
- Set engine parameters
- Load signatures
- Scan

Data structures

See *flow_normal_sgin_bm_scan.pdf*

Test case

test.txt

```
STARToooTESTkkkMYOtestTEST
```

ndb test

create ndb signature for test.txt

format

MalwareName:TargetType:Offset:HexSignature

where TargetType is one of the following numbers specifying the type of the target file:

0: Any file
1: Portable Executable
2: OLE2 component (eg: VBA script)
3: HTML (normalized)
4: Mail File
5: Graphics
6: ELF
7: ASCII text file (normalized)

And Offset is an asterisk or a decimal number n possibly combined with a special modifier:

- * = any
- n = absolute offset
- EOF-n = end of file minus n bytes

Signatures for PE and ELF files additionally support:

- EP+n = entry point plus n bytes (EP+0 for EP)
- EP-n = entry point minus n bytes
- Sx+n = start of section x's (counted from 0) data plus n bytes
- Sx-n = start of section x's data minus n bytes
- SL+n = start of last section plus n bytes
- SL-n = start of last section minus n bytes

All the above offsets except * can be turned into **floating offsets** and represented as Offset,MaxShift where MaxShift is an unsigned integer. A floating offset will match every offset between Offset and Offset+MaxShift, eg. 10,5 will match all offsets from 10 to 15 and EP+n,y will match all offsets from EP+n to EP+n+y. Versions of ClamAV older than 0.91 will silently ignore the MaxShift extension and only use Offset.

HexSignature

Wildcards

ClamAV supports the following extensions inside hex signatures:

- ??

Match any byte.

• a?
Match a high nibble (the four high bits). **IMPORTANT NOTE:** The nibble matching is only available in libclamav with the functionality level 17 and higher therefore please only use it with .ndb signatures followed by ":17" (MinEngineFunctionalityLevel, see 2.3.4).
• ?a
Match a low nibble (the four low bits).
• *
Match any number of bytes.
• {n}
Match n bytes.
• {-n}
Match n or less bytes.
• {n-}
Match n or more bytes.
• (aa|bb|cc|..)
Match aa or bb or cc..
• HEXSIG[x-y]aa or aa[x-y]HEXSIG
Match aa anchored to a hex-signature, see https://wwws.clamav.net/bugzilla/show_bug.cgi?id=776 for a discussion and examples.
The range signatures * and {} virtually separate a hex-signature into two parts, eg. aabbcc*bbaacc is treated as two sub-signatures aabbcc and bbaacc with any number of bytes between them. It's a requirement that each sub-signature includes a block of two static characters somewhere in its body.

```
user@ubuntu:~/clamav$ sigtool --hex-dump
ooo*kkk
6f6f6f2a6b6b6b
File test.ndb
test_ndb_regex:0:3,5:6f6f6f{4}6b6b6b
sudo cp test.ndb /var/lib/clamav/test.ndb
```

Above is a regex based signature with offset info, so it will be loaded into ac pattern structure and will be used in ac scan mode.
The virus record will match start offset between 3 and 8 with pattern as "ooo{4}kkk"(i.e.: any file with sub string "ooo'any 4 bytes'kkk" with the sub string's start at any position between absolute offset 3 and 8 will be identified as virus file)

run

```

cli_ac_addpatt //*
filter_add_acpatt
cli_caloff //*

the loading:

this signature "test_ndb_regex:0:3,5:6f6f6f{4}6b6b6b" has regular expression involved, so should be loaded into AC scan sturcture.

Meanwhile, if the signature doesn't specific a target type, it should be loaded to root[0](generic).

During the db loading process, filter_add_acpatt would be called to calculate prefiltering(using shift or FSM) data of the signatures which will speed up following bm scan a little bit.

load for ndb

```
#define NDB_TOKENS 6 // NDB have 6 fields
cli_loadndb
    cli_initroots
        for(i = 0; i < CLI_MTARGETS; i++) {

```

Scan

scan logic design

there are 4 scan methods

1. BM
2. AC
3. Hash
4. Bytecode

There are 2 entry points to begin a scan: cli_map_scandesc and cli_magic_scandesc
cli_map_scandesc will scan a file that is mapped to virtual memory already, this method is not yet used except in unit test case.
cli_magic_scandesc however is used for now as the primary entry of a scan and actually in a later stage, the file to be scanned will be mapped to memory also.

Before the actual scan, the type of the file is assumed as CL_TYPE_ANY, and the actual type of the incoming file would be decided with cli_filetype2 at magic_scandesc

After the filetype is decided, specific scan function dedicated to the file will be called directly. However, for ASCII file, - CL_TYPE_TEXT_ASCII, the scan will only be called with certain config. So for ascii file, cli_scanraw will be called to make the scan.

In raw scan, ASCII type will be assumed as CL_TYPE_ANY again and calling cli_fmap_scandesc to do further scan.

In cli_fmap_scandesc, according to **ftonly**(if configured as scan specific file type only) and **ftype**(the type of the file which will further decide the root to load) to decide the db to load and scan algo to use in match_run:

- Generic db or type specific db
- BM(normal signature mode or offset mode, currently off mode is only enabled for PE type) or AC or Hash scan
- Hash scan will be performed if BM and AC scan return clean
- If hash scan is clean also, then logic code scan/bytecode scan will be performed via calling cli_lsig_eval and further cli_magic_scandesc_type(mormal BM/AC scan), matchicon or cli_bytecode_runlsig(bytecode scan)
- Bytecode scan will be run finally via cli_bytecode_run
- Bytecode scan can also be triggered via cli_pdf and cli_scanpe
- The bytecode scan will be finally done at cli_vm_execute

In matcher_run, a prefiltering(filter_search_ext) is called to reduce the length of actual scan if possible. After that, BM scan firstly and AC scan later is performed to match against the virus db loaded

The ac scan

```
================== call stack ==================
scanfile
    cl_scandesc_callback
        scan_common
            cli_magic_scandesc
                magic_scandesc // type=CL_TYPE_ANY
```

if(!(ctx->options&~CL_SCAN_ALLMATCHES) || (ctx->recursion == ctx->engine->maxreclevel)) // no for this case

cli_fmap_scandesc // no for this case

if(type != CL_TYPE_IGNORED && ctx->engine->sdb) // no

cli_scanraw // no

case CL_TYPE_TEXT_ASCII: // yes

if(SCAN_STRUCTURED && (DCONF_OTHER & OTHER_CONF_DLP)) // no

cli_scan_structured // no

if(type != CL_TYPE_IGNORED && (type != CL_TYPE_HTML || !(DCONF_DOC & DOC_CONF_HTML_SKIPRAW)) && !ctx->engine->sdb) // yes

cli_scanraw // yes

cli_fmap_scandesc

matcher_run(groot, buff, bytes, &virname, &gdata, offset, &info, ftype, ftoffset, acmode, acres, map, NULL, &viroffset, ctx);

```
if((ret == CL_VIRUS && !SCAN_ALL) || ret == CL_EMEM) {
cli_ac_freedata(&gdata);
if(troot) {
    cli_ac_freedata(&tdata);
    if(bm_offmode)
    cli_bm_freeoff(&toff);
}
if(info.exeinfo.section)
    free(info.exeinfo.section);
cli_hashset_destroy(&info.exeinfo.vinfo);
return ret;
} else if((acmode & AC_SCAN_FT) && ret >= CL_TYPENO) {
if(ret > type)
    type = ret;
}
```

cli_ac_scanbuff

some prerequisite functions

========== ac_findmatch ==========

```
/*
    this function will match a buffer against sigs and dealing with special cases
        boundary
        line marker
        wildcard(ignore, alternative, etc…)
*/
match = 1;
// I is the position of leaf
for(i = pattern->depth; i < pattern->length && bp < length; i++)
/*
    the current support for string alternatives uses a brute-force
    approach and doesn't perform any kind of verification and
    backtracking. This may easily lead to false negatives, eg. when
```

```
        an alternative contains strings of different lengths and
        more than one of them can match at the current position.
*/
        // match it between buffer and current sig
        AC_MATCH_CHAR(pattern->pattern[i],buffer[bp]);
            if(!match) return 0; // no match
            bp++;
// match boundary and line marker
if(pattern->boundary & AC_BOUNDARY_LEFT)
if(pattern->boundary & AC_BOUNDARY_RIGHT)
if(pattern->boundary & AC_LINE_MARKER_LEFT)
if(pattern->boundary & AC_LINE_MARKER_RIGHT)
// match ignore for sig body - ch[1]
if(!(pattern->ch[1] & CLI_MATCH_IGNORE))
        for(i = pattern->ch_mindist[1]; i <= pattern->ch_maxdist[1]; i++)
            AC_MATCH_CHAR(pattern->ch[1],buffer[bp]);
// match prefix
if(pattern->prefix)
        for(i = 0; i < pattern->prefix_length; i++)
            AC_MATCH_CHAR(pattern->prefix[i],buffer[bp]);
// match ignore for sig prefix - ch[0]
if(!(pattern->ch[0] & CLI_MATCH_IGNORE))
        for(i = pattern->ch_mindist[0]; i <= pattern->ch_maxdist[0]; i++)
            AC_MATCH_CHAR(pattern->ch[0],buffer[bp]);

================== ac_addtype ==================
/*
        the story of file type and it's journey along the scan flow
*/

/*
struct cli_matched_type {
    struct cli_matched_type *next;
    off_t offset;
    cli_file_t type;
    unsigned short cnt;
};
```

about the scan, there are two situation

1. before the scan, the file's type is known
2. before the scan, the file type is unknown(zip file or ole file and etc…)

for 1, just call the dedicated scan function

for 2, need to do a so called raw scan first to decide the file type embedded into current raw file, and any file type identified in this round of scan will be stored in data structure cli_matched_type

this function ‘ac_addtype’ is called only at cli_ac_scanbuff as raw scan will finally call cli_ac_scanbuff to identify the possible file’s types in side any raw file

*/

/*
in this function. if detect file types on the fly(raw scan), add the type to matched type list. say if found PE file inside ZIP file match’s current sig, then need to add ZIP and PE both to the list for future target specific scan in cli_scanraw at libclamav/scanners.c

and the flow is:
the cli_scanraw, first scan called at cli_fmap_scandesc will be identify any specific file types inside the raw file. after cli_fmap_scandesc returns, if identified no virus during the scan and instead identified specific file types inside the raw file, then will call the target specific scan according to the file type ideniftied.

in cli_ac_scanbuff, the return will be as bellow if no virus is detected in case of raw scan:
return (mode & AC_SCAN_FT) ? type : CL_CLEAN;
according to the scan mode to decide the return value

and bellow is the full story of AC_SCAN_FT:
1. in magic_scandesc
uint8_t typercg = 1; // means need type recognition, it will be set by default as 1 and can only be unset if target file type is zip or archive and has a size over 1MB; also this value ‘1’ will be used in following raw scan if target file’s type is yet to be determined

```
// not doing AC_SCAN_FT for first scanraw call
ret = cli_scanraw(ctx, type, 0, &dettype, hash)

 switch(type)
    // if already identified the file types, call the type dedicated scan function
    //otherwise, call cli_scanraw to decide the file type with ‘typercg=1’
 … …

 // Not checking for embedded PEs (zip file > 1 MB)
 if(type == CL_TYPE_ZIP && SCAN_ARCHIVE && (DCONF_ARCH & ARCH_CONF_ZIP))
 if((*ctx->fmap)->len > 1048576) typercg = 0;

// doing AC_SCAN_FT for second cli_scanraw call
res = cli_scanraw(ctx, type, typercg, &dettype, hash);
```

// in raw scan will call cli_fmap_scandesc

// in this function, when doing scan, will decide to do file type recognition scan according to the value of typercg

// if during the raw scan initialized cli_fmap_scandesc, if virus is identified, will count it as a match, otherwise, if no virus is identified and new file type is identified on the fly, after return, will do specified file type scan in cli_scanraw

2. in cli_scanraw

```
int ret = CL_CLEAN, nret = CL_CLEAN;
unsigned int acmode = AC_SCAN_VIR // by default is scan virus mode

if(typercg) // if have typergc defined, will do file type recognition
    acmode |= AC_SCAN_FT;

// bellow scan will do two things
// 1. scan for virus in the raw file
// 2. identify any file types inside the raw file
ret = cli_fmap_scandesc(ctx, type == CL_TYPE_TEXT_ASCII ? 0 : type, 0, &ftoffset, acmode, NULL, refhash);

// if identified certain file types of the raw file
```

```
#define CL_TYPENO 500
#define MAX_EMBEDDED_OBJ 10

typedef enum {
    CL_TYPE_ANY = 0,
    CL_TYPE_TEXT_ASCII = CL_TYPENO, /* X3.4, ISO-8859, non-ISO ext. ASCII */
    CL_TYPE_TEXT_UTF8,
```

```
if(ret >= CL_TYPENO) // not CL_TYPE_ANY and CL_TYPE_TEXT_ASCII
    //recursively scan, as this is another level inside the raw scan
    ctx->recursion++;
    if(nret != CL_VIRUS) // don't need this if test, as: nret == CL_CLEAN
```

```
/* return codes */

                        //try next pattern in next_same list
                        pt = pt->next_same;continue;
                  /* it's a partial signature, no for this case */
                  if(pt->sigid)
                    // TBD TBD TBD

                  /* old type signature, yes for this case */
                  else
                    // old type sig

                  //try next pattern in next_same list

        // try next pattern in leaf node, end of while
//return identified file type if it's a AC_SCAN_FT scan
return (mode & AC_SCAN_FT) ? type : CL_CLEAN;

================== old type sig ====================
else
  if(pt->type) // matched sig is for specific file types
    // if current sig's type is marked as ignored
    // and '!pt->rtype' means current sig has no prerequisite type( means this is a scan
for virus instead of load file types) or current sig's prerequisite type is the same type
as file to be scanned
    // then even we had a match, let's ignore
    if(pt->type == CL_TYPE_IGNORED && (!pt->rtype || ftype == pt->rtype)) return
CL_TYPE_IGNORED;

/*
      Before going any further, let's talk about loading file types
      If look for daily.ftm and sees this line:
      0:0:52656365697665643a20:Raw mail:CL_TYPE_ANY:CL_TYPE_MAIL
       It means that if ClamAV sees "Received:" as THE FIRST LINE then it sets the
       scanning type to "Mail" (type 4 signatures)
       Means in cli_loadftm
       tokens[4]=CL_TYPE_ANY
       tokens[5]=CL_TYPE_MAIL
       ==============================
      look at the example in daily:
```

sigtool --unpack-current daily
cat daily.ftm

0:0:425a68:BZip:CL_TYPE_ANY:CL_TYPE_BZ
0: this is a static signature (no wildcards), anchored at an offset
0: offset 0
425a68: the hex signature
Bzip: description of file format (used in --debug output)
CL_TYPE_ANY: prerequisite filetype
CL_TYPE_BZ: the filetype

1:*:504b0304:ZIP-SFX:CL_TYPE_ANY:CL_TYPE_ZIPSFX
1: arbitrary offset/wildcard enabled
*: any offset
504b0304: hex signature
ZIP-SFX: description
CL_TYPE_ANY: prerequisite filetype
CL_TYPE_ZIPSFX: the filetype
==========
Story of rtype and type
In normal case, both rtype and type passed into cli_ac_scanbuff is 0, and rtype and type is set only at cli_loadftm while loading file formats from *.ftm db
rtype = cli_ftcode(tokens[4]); - prerequisite file type
type = cli_ftcode(tokens[5]); - the target filetype
ret = cli_parse_add(engine->root[0], tokens[3], tokens[2], rtype, type, tokens[1], 0, NULL, options)

==========
In cli_ac_scanbuff, type would log the match status and initialized as CL_CLEAN

```
/* return codes */
typedef enum {
    /* libclamav specific */
    CL_CLEAN = 0,
    CL_SUCCESS = 0,
    CL_VIRUS,
    CL_ENULLARG,
```

*/
/*
pt->type > type : first scan to compare against type which is inited as CL_CLEAN
pt->type >= CL_TYPE_SFX : complicated types
pt->type == CL_TYPE_MSEXE : PE file
!pt->rtype: no prerequisite type, virus scan instead of load file type scan
ftype == pt->rtype : target file type matching sig's target type
so bellow if judgment means
if sig's target type is a complicated one
and it's a virus scan or current file type matches sig's target type

```
   */
   if((pt->type > type || pt->type >= CL_TYPE_SFX || pt->type == CL_TYPE_MSEXE)
&& (!pt->rtype || ftype == pt->rtype))
      // matched the condition, so update the type with sig's target type
      type = pt->type;
      /*
          Here, 'ftoffset' is a pointer points to a pointer
          So bellow if judgment means:
              If there's ** offset pointer
              *offset is not pointing anywhere or sig's target type is a legal embedded
file or a zip SFX file
              and sig's target type is SFX file or target file type is PE or ZIP or OLE file
with sig's target type as MS EXE
          so here the logic is: if in raw scan, if certain offset in the target file is
matched against a sig type, will add it to the ftoffset list and use it in future target
specified scan
      */
      if(ftoffset && (!*ftoffset || (*ftoffset)->cnt < MAX_EMBEDDED_OBJ || type ==
CL_TYPE_ZIPSFX) && (type >= CL_TYPE_SFX || ((ftype == CL_TYPE_MSEXE || ftype
== CL_TYPE_ZIP || ftype == CL_TYPE_MSOLE2) && type == CL_TYPE_MSEXE)))
         // add it to ftoffset chain
         // means adding one more target type to the future scan list
         ac_addtype(ftoffset, type, realoff, ctx)

 else// matched sig is for general type
    if(pt->lsigid[0])
       // match sub sigs
       // TBD TBD TBD
       lsig_sub_matched(root, mdata, pt->lsigid[1], pt->lsigid[2], realoff, 0);
       //try next pattern in next_same list
    // there's a match to report
    if(res) // report to the result structure
       //try next pattern in next_same list
    else
       if(virname) // just report virus name
          // match all sig's even has a match at current sig
          if (ctx && SCAN_ALL && virname == ctx->virname)
              cli_append_virus(ctx, pt->virname);
          else *virname = pt->virname;
       // no need to match all sigs, just find and return
       if (!ctx || !SCAN_ALL) return CL_VIRUS;
       else // try next pattern in next_same list
```
